Maintainer Emilio S. Guillen < Emilio. Saenz-Guillen@bayes.city.ac.uk >

Description Spline Regression, Generalized Additive Models, and Component-wise Gradient Boosting, utilizing Geometrically Designed (GeD) Splines. GeDS regression is a non-parametric method inspired by geometric principles, for fitting spline regression models with variable knots in one or two independent variables. It efficiently estimates the number of knots and their positions, as well as the spline order, assuming the response variable follows a distribution from the exponential family. GeDS models integrate the broader category of Generalized (Non-)Linear Models, offering a flexible approach to modeling complex relationships. A description of the method can be found in Kaishev et al. (2016) <doi:10.1007/s00180-015-0621-7> and Dimitrova et al. (2023) <doi:10.1016/j.amc.2022.127493>. Further extending its capabilities, GeDS's implementation includes Generalized Additive Models (GAM) and Functional Gradient Boosting (FGB), enabling versatile multivariate predictor modeling, as discussed in the forthcoming work of Dimitrova et al. (2024).

GeDS-package 3

GeDS-package GeDS

# Description

Geometrically Designed Splines (GeDS) regression is a non-parametric method inspired by geometric principles, which is designed for fitting spline predictor models with variable knots. This method falls within the domain of generalized non-linear models (GNM), which include generalized linear models (GLM) as a special case. GeDS regression is fitted based on a sample of N observations of a response variable y, dependent on a set of (currently up to two) covariates, assuming y has a distribution from the exponential family. In addition, GeDS methodology is implemented both in the context of Generalized Additive Models (GAM) and Functional Gradient Boosting (FGB). On the one hand, GAM consist of an additive modeling technique where the impact of the predictor variables is captured through smooth (GeDS, in this case) functions. On the other hand, GeDS incorporates gradient boosting machine learning technique by implementing functional gradient descent algorithm to optimize general risk functions utilizing component-wise GeDS estimates.

#### **Details**

The GeDS estimation method is based on: first constructing a piecewise linear fit (spline fit of order 2) at stage A which captures the shape of the data and; second approximating this fit with shape preserving (variation diminishing) spline fits of higher orders 3, 4,... (i.e., degrees 2, 3,...) at stage B. As a result of this, GeDS estimates the number and location of the knots and the order of the spline fit in a fast and efficient way.

The GeDS method was originally developed by Kaishev et al. (2016) assuming the response variable y to be normally distributed and a corresponding *Mathematica* code was provided.

The GeDS method was extended by Dimitrova et al. (2023) to cover any distribution from the exponential family. The **GeDS** R package presented here includes an enhanced R implementation of the original Normal GeDS *Mathematica* code due to Kaishev et al. (2016), implemented as the NGeDS function and a generalization of it in the function GGeDS which covers the case of any distribution from the exponential family.

The **GeDS** package allows also to fit two dimensional response surfaces and to construct multivariate (predictor) models with a GeD spline component and a parametric component (see the functions f, formula, NGeDS and GGeDS for details).

Dimitrova et al. (2024) have recently made significant enhancements to the **GeDS** methodology, to incorporate generalized additive models (GAM) and functional gradient boosting (FGB). On the one hand, generalized additive models are encompassed by implementing the *local-scoring* algorithm using normal GeD splines (i.e., NGeDS) as function smoothers within the *backfitting* iterations. This is implemented via the function NGeDSgam. On the other hand, the **GeDS** package incorporates the functional gradient descent algorithm by utilizing normal GeD splines (i.e., NGeDS) as base learners. This is implemented via the function NGeDSboost.

The outputs of both NGeDS and GGeDS functions are GeDS-class objects, while the outputs of NGeDSgam and NGeDSboost are GeDSgam-class and GeDSboost-class objects, respectively. As described in Kaishev et al. (2016), Dimitrova et al. (2023) and Dimitrova et al. (2024), the final

4 GeDS-package

GeDS fit is the one whose order is chosen according to a strategy described in stage B of the algorithm. However, GeDS-class, GeDSgam-class and GeDSboost-class objects contain second, third and fourth order spline fits and the user has the possibility to choose among them.

The **GeDS** package also includes some datasets where GeDS regression proves to be very efficient and some user friendly functions that are designed to easily extract required information. Several methods are also provided to handle GeDS, GAM-GeDS and FGB-GeDS output results (see GeDS-class, GeDSgam-class and GeDSboost-class, respectively).

Throughout this document, we use the terms GeDS predictor model, GeDS regression and GeDS fit interchangeably.

Please report any issue arising or bug in the code to <emilio.saenz-guillen@bayes.city.ac.uk>.

BaFe2As2 5

BaFe2As2

Barium-Ferrum-Arsenide Powder Diffraction Data

# Description

This dataset contains the results of a neutron diffraction experiment on Barium-Ferrum-Arsenide ( $BaFe_2As_2$ ) powder carried out by Kimber et al. (2009) and used in Kaishev et al. (2016). The neutron diffraction intensity was measured at 1,151 different dispersion angles in order to model the diffraction profile.

# Usage

```
data(BaFe2As2)
```

#### **Format**

A data. frame with 1151 cases and 2 variables:

angle the dispersion angle, viewed as the independent variable.

intensity the neutron diffraction intensity, viewed as the response variable.

6 BivariateFitters

BivariateFitters

Fitter function for GeD Spline Regression for bivariate data

# **Description**

These are computing engines called by NGeDS, needed for the underlying fitting procedures.

# Usage

```
BivariateFitter(
 Χ,
  Υ,
 Ζ,
 W,
 weights = rep(1, length(X)),
  Indicator,
 beta = 0.5,
 phi = 0.99,
 min.intknots = 0,
 max.intknots = 300,
  q = 2,
  Xextr = range(X),
  Yextr = range(Y),
  show.iters = TRUE,
  tol = as.double(1e-12),
  stoptype = c("SR", "RD", "LR")
GenBivariateFitter(
 Χ,
  Υ,
  Ζ,
 W,
  family = family,
 weights = rep(1, length(X)),
  Indicator,
  beta = 0.5,
  phi = 0.5,
 min.intknots = 0,
 max.intknots = 300,
  q = 2,
  Xextr = range(X),
 Yextr = range(Y),
  show.iters = TRUE,
  tol = as.double(1e-12),
  stoptype = c("SR", "RD", "LR")
)
```

BivariateFitters 7

# Arguments

X	a numeric vector containing $N$ sample values of the first independent variable chosen to enter the spline regression component of the predictor model.
Υ	a numeric vector containing $N$ sample values of the second independent variable chosen to enter the spline regression component of the predictor model.
Z	a vector of size $N$ containing the observed values of the response variable.
W	a design matrix with $N$ rows containing other covariates selected to enter the parametric component of the predictor model (see <code>formula</code> ). If no such covariates are selected, it is set to NULL by default.
weights	an optional vector of size $N$ of 'prior weights' to be put on the observations in the fitting process in case the user requires weighted GeDS fitting. It is NULL by default.
Indicator	contingency table of X and Y.
beta	numeric parameter in the interval $[0,1]$ tuning the knot placement in stage A of GeDS. See the description of NGeDS or GGeDS.
phi	numeric parameter in the interval $[0,1]$ specifying the threshold for the stopping rule (model selector) in stage A of GeDS. See also stoptype and details in the description of NGeDS or GGeDS.
min.intknots	optional parameter allowing the user to set a minimum number of internal knots required. By default equal to zero.
max.intknots	optional parameter allowing the user to set a maximum number of internal knots to be added by the GeDS estimation algorithm. By default equal to the number of internal knots $\kappa$ for the saturated GeDS model (i.e. $\kappa=N-2$ ).
q	numeric parameter which allows to fine-tune the stopping rule of stage A of GeDS, by default equal to 2. See details in the description of NGeDS or GGeDS.
Xextr	boundary knots in the X direction. By default equal to the range of X.
Yextr	boundary knots in the Y direction. By default equal to the range of Y.
show.iters	logical variable indicating whether or not to print information at each step. By default equal to FALSE.
tol	numeric value indicating the tolerance to be used in checking whether two knots should be considered different during the knot placement steps in stage A.
stoptype	a character string indicating the type of GeDS stopping rule to be used. It should be either "SR", "RD" or "LR", partial match allowed. See details of NGeDS or GGeDS.
family	a description of the error distribution and link function to be used in the model. This can be a character string naming a family function (e.g. "gaussian"), the family function itself (e.g. gaussian) or the result of a call to a family function (e.g. gaussian()). See family for details on family functions.

# Value

A GeDS-Class object, but without the Formula, extcall, terms and znames slots.

bl\_imp.GeDSboost

Base Learner Importance for GeDSboost objects

# **Description**

This function calculates the in-bag mean squared error (MSE) reduction ascribable to each of the base-learners with regards to the final prediction of the component-wise gradient boosted model encapsulated in a GeDSboost-Class object. Essentially, it measures the decrease in MSE attributable to each base-learner for every time it is selected across the boosting iterations, and aggregates them. This provides a measure on how much each base-learner contributes to the overall improvement in the model's accuracy, as reflected by the decrease in MSE. This function is adapted from varimp and is compatible with the available mboost-package methods for varimp, including plot, print and as.data.frame.

# Usage

```
## S3 method for class 'GeDSboost'
bl_imp(object, ...)
```

# **Arguments**

object An object of class GeDSboost-Class.
... potentially further arguments.

#### **Details**

See varimp for details.

# Value

An object of class varimp with available plot, print and as.data.frame methods.

coalMining

Coal Mining Disasters data

# Description

A dataset with 112 entries containing annual numbers of accidents due to disasters in British coal mines for years from 1850 to 1962, considered in Carlin et al. (1992) and also in Eilers and Marx (1996).

# Usage

```
data(coalMining)
```

# Format

A data. frame with 112 entries, corresponding to the years from 1850 to 1962. Each entry has:

accidents number of severe accidents that have occurred each year.

years year during which accidents occurred.

# Source

```
https://people.reed.edu/~jones/141/Coal.html

coef.GeDS

Coef method for GeDS objects

# Description

Methods for the functions coef and coefficients that allow to extract the estimated coefficients of a fitted GeDS regression from a GeDS-Class object.

# Usage

```
## S3 method for class 'GeDS'
coef(object, n = 3L, onlySpline = TRUE, ...)
## S3 method for class 'GeDS'
coefficients(object, n = 3L, onlySpline = TRUE, ...)
```

# **Arguments**

object	the GeDS-class object from which the coefficients of the selected GeDS regression should be extracted.
n	integer value $(2, 3 \text{ or } 4)$ specifying the order $(= \text{degree} + 1)$ of the GeDS fit whose coefficients should be extracted. By default equal to 3L. Non-integer values will be passed to the function as.integer.
onlySpline	logical variable specifying whether only the coefficients for the GeDS component of the fitted multivariate regression model should be extracted or alternatively also the coefficients of the parametric component should also be extracted.
	potentially further arguments (required by the definition of the generic function). They will be ignored, but with a warning.

# **Details**

These are simple methods for the functions coef and coefficients.

As GeDS-class objects contain three different fits (linear, quadratic and cubic), it is possible to specify the order of the fit for which GeDS regression coefficients are required via the input argument n.

As mentioned in the details of formula, the predictor model may be multivariate and it may include a GeD spline component whereas the remaining variables may be part of a parametric component. If the onlySpline argument is set to TRUE (the default value), only the coefficients corresponding to the GeD spline component of order n of the multivariate predictor model are extracted.

coef.GeDSboost,gam 11

#### Value

A named vector containing the required coefficients of the fitted multivariate predictor model. The coefficients corresponding to the variables that enter the parametric component of the fitted multivariate predictor model are named as the variables themselves. The coefficients of the GeDS component are coded as "N" followed by the index of the corresponding B-spline.

#### See Also

coef for the standard definition; NGeDS for examples.

# **Examples**

```
# Generate a data sample for the response variable
# and the covariates
set.seed(123)
N <- 500
f_1 \leftarrow function(x) (10*x/(1+100*x^2))*4+4
X \leftarrow sort(runif(N, min = -2, max = 2))
Z <- runif(N)</pre>
# Specify a model for the mean of the response Y to be a superposition of
\# a non-linear component f_1(X), a linear component 2*Z and a
# free term 1, i.e.
means \leftarrow f_1(X) + 2*Z + 1
# Add normal noise to the mean of y
Y \leftarrow rnorm(N, means, sd = 0.1)
# Fit to this sample a predictor model of the form f(X) + Z, where
\# f(X) is the GeDS component and Z is the linear (additive) component
# see ?formula.GeDS for details
(Gmod \leftarrow NGeDS(Y \sim f(X) + Z, beta = 0.6, phi = 0.995, Xextr = c(-2,2)))
# Extract the GeD spline regression coefficients
coef(Gmod, n = 3)
# Extract all the coefficients, including the one for the linear component
coef(Gmod, onlySpline = FALSE, n = 3)
```

 ${\tt coef.GeDSboost,gam}$ 

Coef method for GeDSboost, GeDSgam

# **Description**

Methods for the functions coef and coefficients that allow to extract the estimated coefficients of GeDSboost-Class or GeDSgam-Class object.

Derive Derive

# Usage

```
## S3 method for class 'GeDSboost'
coef(object, n = 3L, ...)

## S3 method for class 'GeDSboost'
coefficients(object, n = 3L, ...)

## S3 method for class 'GeDSgam'
coef(object, n = 3L, ...)

## S3 method for class 'GeDSgam'
coefficients(object, n = 3L, ...)
```

# **Arguments**

the GeDSboost-class or GeDSgam-Class object from which the coefficients should be extracted.

n integer value (2, 3 or 4) specifying the order (= degree +1) of the FGB-GeDS/GAM-GeDS fit whose coefficients should be extracted. If n = 2L piecewise polynomial coefficients of the univariate GeDS base-learners are provided. In the case of bivariate GeDS base learners and class(object) == "GeDSboost", the B-spline coefficients for each iteration where a particular base-learner was selected are provided. In the case of bivariate base learners and class(object) == "GeDSgam", the final local-scoring B-spline coefficients for each base-learner are provided. If n = 3L or n = 4L B-spline coefficients are provided. By default n is equal to 3L. Non-integer values will be passed to the function as.integer.

... potentially further arguments (required by the definition of the generic function).

#### Value

A named vector containing the required coefficients of the fitted multivariate predictor model.

# See Also

coef for the standard definition; NGeDSboost and NGeDSgam for examples.

Derive Derivative of GeDS objects

They will be ignored, but with a warning.

# **Description**

This function computes derivatives of a fitted GeDS regression model.

# Usage

```
Derive(object, order = 1L, x, n = 3L)
```

Derive 13

# **Arguments**

object	the GeDS-Class object containing the GeDS fit which should be differentiated. It should be the result of fitting a univariate GeDS regression via NGeDS or GGeDS.
order	integer value indicating the order of differentiation required (e.g. first, second or higher derivatives). Note that order should be lower than n and that non-integer values will be passed to the function as.integer.
X	numeric vector containing values of the independent variable at which the derivatives of order order should be computed.
n	integer value $(2, 3 \text{ or } 4)$ specifying the order $(= \text{degree} + 1)$ of the GeDS fit to be differentiated. By default equal to 3L.

# **Details**

The function is based on splineDesign and it computes the exact derivative of the fitted GeDS regression.

The function uses the property that the m-th derivative of a spline, m=1,2,..., expressed in terms of B-splines can be computed by differentiating the corresponding B-spline coefficients (see e.g. De Boor, 2001, Chapter X, formula (15)). Since the GeDS fit is a B-spline representation of the predictor, it cannot work on the response scale in the GNM (GLM) framework.

# References

De Boor, C. (2001). A Practical Guide to Splines (Revised Edition). Springer, New York.

# Examples

```
# Generate a data sample for the response variable
# Y and the covariate X
set.seed(123)
N <- 500
f_1 \leftarrow function(x) (10*x/(1+100*x^2))*4+4
X \leftarrow sort(runif(N, min = -2, max = 2))
# Specify a model for the mean of Y to include only
# a component non-linear in X, defined by the function f_1
means \leftarrow f_1(X)
# Add (Normal) noise to the mean of Y
Y \leftarrow rnorm(N, means, sd = 0.1)
# Fit GeDS regression with only a spline component in the predictor model
Gmod <- NGeDS(Y ~ f(X), beta = 0.6, phi = 0.995, Xextr = c(-2,2))
# Compute the second derivative of the cubic GeDS fit
# at the points 0, -1 and 1
Derive(Gmod, x = c(0, -1, 1), order = 2, n = 4)
```

14 deviance.GeDS

deviance.GeDS	Deviance method for GeDS, GeDSboost, GeDSgam	
deviance.GeDS	Deviance method for GeDS, GeDSboost, GeDSgam	

# **Description**

Method for the function deviance that allows the user to extract the value of the deviance corresponding to a selected GeDS, GeDSboost or GeDSgam fit from a GeDS-Class, GeDSboost-Class or GeDSgam-Class object.

# Usage

```
## S3 method for class 'GeDS'
deviance(object, n = 3L, ...)

## S3 method for class 'GeDSboost'
deviance(object, n = 3L, ...)

## S3 method for class 'GeDSgam'
deviance(object, n = 3L, ...)
```

# **Arguments**

object	the GeDS-class, GeDSboost-class or GeDSgam-class object from which the deviance should be extracted.
n	integer value $(2, 3 \text{ or } 4)$ specifying the order $(= \text{degree} + 1)$ of the GeDS/GeDSboost/GeDSgam fit whose deviance should be extracted. By default equal to 3L. Non-integer values will be passed to the function as.integer.
• • •	potentially further arguments (required by the definition of the generic function). They will be ignored, but with a warning.

# **Details**

This is a method for the function deviance. As GeDS-class, GeDSboost-class and GeDSgam-class objects contain three different fits (linear, quadratic and cubic), it is possible to specify the order of the GeDS fit for which the deviance is required via the input argument n.

#### Value

A numeric value corresponding to the deviance of the selected GeDS/GeDSboost/GeDSgam fit. #'

# See Also

deviance for the standard definition; GGeDS for examples.

EWmortality 15

EWmortality Death counts in England and Wales	
---	--

# **Description**

The dataset consists of information about the mortality of the English and Welsh male population aggregated over the years 2000, 2001 and 2002.

# Usage

```
data(EWmortality)
```

#### **Format**

A data. frame with 109 entries and 3 variables: Age, Deaths and Exposure. Exposure is a mid-year estimate of the population exposed to risk.

f

Defining the covariates for the spline component in a GeDS formula.

# **Description**

In general the GeDS predictor model may include a GeD spline regression component with respect to part of the independent variables and a parametric component in which the remaining covariates may enter as additive terms.

The function f is to be used in the formula argument of NGeDS or GGeDS in order to specify which independent variables (covariates) should be included in the GeD spline regression component of the predictor model.

# Usage

```
f(x, xx = NULL, ...)
```

# **Arguments**

X	numeric vector containing $N$ sample values of the covariate chosen to enter the spline regression component of the predictor model.
xx	numeric vector containing $N$ sample values for the second covariate (in case NGeDS is run for two dimensions). It has to be either NULL (the default) or a vector of size $N$ , same as $\mathbf{x}$ .
	further arguments. As GeDS currently allows for up to two covariates, specification of further arguments will return an error.

16 formula.GeDS

#### Note

This function is intended to be used only as part of the formula in a GeDS regression via NGeDS or GGeDS and not to be called in other cases by the user.

#### See Also

NGeDS; GGeDS.

# **Examples**

```
# Generate a data sample for the response variable Y and
# the covariates X, reg1, reg2 and off
set.seed(123)
N <- 500
f_1 \leftarrow function(x) (10*x/(1+100*x^2))*4+4
X \leftarrow sort(runif(N , min = -2, max = 2))
reg1 <- runif(500, min = -0.1, max = 0.1)
reg2 <- runif(500, min = -0.2, max = 0.2)
off \leftarrow runif(500, min = -1, max = 1)
# Specify a model for the mean of Y to include a component non linear
\# in X defined by the function f_1 and a linear one in the other covariates
means \leftarrow f_1(X) + 2*reg1 + 0.5*reg2 + off
# Add Normal noise to the mean of Y
Y \leftarrow rnorm(N, means, sd = 0.1)
# Specify a formula that will be used to model Y as a
# function of X, reg1, reg2 and off.
# The covariate X is for the spline component modeled as GeDS,
# reg1 and reg2 enter linearly, off is an offset, i.e. no coefficient
# will be estimated for it
formula \leftarrow Y \sim f(X) + reg1 + reg2 + offset(off)
# Fit a GeDS model specified in formula using NGeDS
(Gmod \leftarrow NGeDS(formula, beta = 0.6, phi = 0.995, Xextr = c(-2,2)))
```

formula.GeDS

Formula for the predictor model

# Description

A description of the structure of a predictor model to be fitted using NGeDS and/or GGeDS and how this information can be extracted from a GeDS-class object.

#### Usage

```
## S3 method for class 'GeDS'
formula(x, ...)
```

GeDS-class 17

# Arguments

x Fitted GeDS-class object, tipically produced by NGeDS or GGeDS from which the predictor model formula should be extracted.

... Unused in this case.

#### **Details**

In the GeDS GNM (GLM) regression, implemented in NGeDS and GGeDS, it is assumed that the mean of the response variable transformed using an appropriate link function is modelled through a possibly multivariate predictor model involving two components: a GeD variable knot spline regression component involving up to two of the independent variables and a parametric component with respect to the remaining independent variables. The formula is used to specify the structure of such a possibly multivariate predictor model.

The formulae that are input in NGeDS and GGeDS are similar to those input in 1m or g1m except that the function f should be specified in order to identify which of the covariates enter the GeD spline regression part of the predictor model. For example, if the predictor model is univariate and it links the transformed means of y to x1, the predictor has only a GeD spline component and the formula should be in the form  $y \sim f(x1)$ .

As noted, there may be additional independent variables, x2, x3, ... which may enter linearly into the parametric component of the predictor model and not be part of the GeD spline regression component. For example one may use the formula  $y \sim f(x1) + x2 + x3$  which assumes a spline regression only between the transformed mean of y and x1, while x2 and x3 enter the predictor model just linearly.

In the current version of the package, GGeDS is univariate, therefore only one covariate which enters the spline regression component can be specified.

In contrast, the function NGeDS, generates also bivariate GeDS regression models. Therefore, if the functional dependence of the mean of the response variable y on x1 and x2 needs to be jointly modelled and there are no other covariates, the formula for the corresponding two dimensional predictor model should be specified as  $y \sim f(x1, x2)$ .

Within the argument formula, similarly as in other R functions, it is possible to specify one or more offset variables, i.e. known terms with fixed regression coefficients equal to 1. These terms should be identified via the function offset.

GeDS-class GeDS Class

# Description

A fitted GeDS object returned by the functions NGeDS or GGeDS inheriting the methods from class "GeDS". Methods for functions coef, knots, print, predict, plot, and lines are available.

18 GeDS-class

#### **Slots**

Type Character string indicating the type of the regression performed. One of "LM - Univ", "LM - Biv" or "GLM - Univ" corresponding to the Normal univariate GeDS, the Normal bivariate GeDS performed by NGeDS and the generalized (GNM-GLM) univariate GeDS performed by GGeDS.

Linear.Knots Vector containing the locations of the knots of the second order GeDS spline fit generated at stage A.

Quadratic.Knots Vector containing the locations of the knots of the third order GeDS spline fitted in stage B.

Cubic.knots Vector containing the locations of the knots of the fourth order GeDS spline fitted in stage B.

Dev. Linear Deviance of the second order GeD spline fit of stage A.

Dev. Quadratic Deviance of the third order GeD spline fit of stage B.

Dev. Cubic Deviance of the fourth order GeD spline fit of stage B.

RSS Vector containing the deviances of the second order spline fits computed at each GeDS iteration in stage A.

Linear List containing the results from running a SplineReg function used to fit the second order spline of stage A.

Quadratic List containing the results from running SplineReg function used to fit the third order spline in stage B.

Cubic List containing the results from a SplineReg function used to fit the fourth order spline in stage B.

Stored Matrix containing the knot locations estimated at each step of stage A.

Args List containing the input arguments passed on the Fitters functions.

Call call to the Fitters functions.

Nintknots The final number of internal knots of the second order GeD spline fit of stage A.

iters Number of iterations performed in stage A of the GeDS fitting procedure.

Guesses Initial values for the coefficients used at each iteration of stage A in order to estimate the spline coefficients. Since the initial values are used only in the IRLS procedure, this slot is empty if the object is not created by GGeDS or GenUnivariateFitter functions.

Coefficients Matrix containing the fitted coefficients of the GeD spline regression component and the parametric component at each iteration of stage A.

deviance Vector containing the deviances of the second order spline fits computed at each IRLS iteration in stage A. Since the IRLS procedure is used only in GGeDS or GenUnivariateFitter, this slot is empty if the object is not created by one of these functions.

iterIrls Vector containing the numbers of IRLS iterations for all iterations of stage A cumulatively. Since the IRLS procedure is used only in GGeDS or GenUnivariateFitter, this slot is empty if the object is not created by one of these functions.

stopinfo List of values providing information related to the stopping rule of stage A of GeDS. The sub-slots of stopinfo are phis, phis\_star, oldintc and oldslp. The sub-slot phis is a vector containing the values of the ratios of deviances (or the difference of deviances if the LR stopping rule was chosen). The sub-slots phis\_star, oldintc and oldslp are non-empty slots if the SR stopping rule was chosen. They contain respectively  $\hat{\phi}_{\kappa}$ ,  $\hat{\gamma}_0$  and  $\hat{\gamma}_1$  computed at each iteration of stage A, see Dimitrova et al. (2023).

GeDSboost-class 19

Formula The model formula.

extcall call to the NGeDS or GGeDS functions.

terms terms object containing information on the model frame.

GeDSboost-class

GeDSboost Class

# **Description**

A fitted GeDSboost object returned by the function NGeDSboost inheriting the methods from class "GeDSboost". Methods for functions coef, knots, print, predict, visualize\_boosting, and bl\_imp are available.

#### **Slots**

extcall call to the NGeDSboost function.

formula A formula object representing the model to be fitted.

args A list containing the arguments passed to the NGeDSboost function. This list includes:

- response: data.frame containing observations of the response variable.
- predictors: data.frame containing observations of the vector of predictor variables included in the model.
- base\_learners: description of model's base learners.
- family: the statistical family. The possible options are

20 GeDSboost-class

```
- mboost::PropOdds(nuirange = c(-0.5, -1), offrange = c(-5, 5))
- mboost::Weibull(nuirange = c(0, 100))
- mboost::Loglog(nuirange = c(0, 100))
- mboost::Lognormal(nuirange = c(0, 100))
- mboost::Gehan()
- mboost::Hurdle(nuirange = c(0, 100))
- mboost::Multinomial()
- mboost::Cindex(sigma = 0.1, ipcw = 1)
- mboost::RCG(nuirange = c(0, 1), offrange = c(-5, 5))
```

- initial\_learner: if TRUE a NGeDS fit was used as initial learner; otherwise, the empirical risk minimizer corresponding to the selected family was employed.
- int.knots\_init: if initial\_learner = TRUE the maximum number of internal knots set to the NGeDS function before the initial learner fit.
- shrinkage: shrinkage/step-length/learning rate utilized throughout the boosting iterations
- normalize\_data: if TRUE, then response and predictors were standardized before running the FGB algorithm.
- X\_mean: mean of the predictor variables (only if normalize\_data = TRUE).
- X\_sd: standard deviation of the predictors (only if normalize\_data = TRUE).
- Y\_mean: mean of the response variable (only if normalize\_data = TRUE).
- Y\_sd: standard deviation of the response variable (only if normalize\_data = TRUE).

models A list containing the 'model' generated at each boosting iteration. Each of these models includes:

- best\_b1: fit of the base learner that minimized the residual sum of squares (RSS) in fitting the gradient at the *i*-th boosting iteration.
- Y\_hat: model fitted values at the *i*-th boosting iteration.
- base\_learners: knots and coefficients for each of the base-learners at the *i*-th boosting iteration.

final\_model A list detailing the final GeDSboost model after the gradient descent algorithm is run. Apart of the components present in any model it includes the quadratic and cubic fits obtained through Schoenberg variation diminishing spline approximation. These include the same elements as Quadratic and Cubic in a GeDS-class object (see SplineReg for details). best\_bl is eliminated to simplify the output.

predictions A list containing the predicted values obtained (linear, quadratic, and cubic).

internal\_knots A list detailing the internal knots obtained for the fits of different order (linear, quadratic, and cubic).

GeDSgam-class 21

GeDSgam-class

GeDSgam Class

# **Description**

A fitted GeDSgam object returned by the function NGeDSgam inheriting the methods from class "GeDSgam". Methods for functions coef, knots, print and predict.

#### **Slots**

extcall call to the NGeDSgam function.

formula A formula object representing the model to be fitted.

args A list containing the arguments passed to the NGeDSgam function. This list includes:

- response: data.frame containing observations of the response variable.
- predictors: data.frame containing observations of the vector of predictor variables included in the model.
- base\_learners: description of the model's base learners ('smooth functions').
- family: the statistical family. The possible options are
  - binomial(link = "logit", "probit", "cauchit", "log", "cloglog")
  - gaussian(link = "identity", "log", "inverse")
  - Gamma(link = "inverse", "identity", "log")
  - inverse.gaussian(link = "1/mu^2", "inverse", "identity", "log")
  - poisson(link = "log", "identity", "sqrt")
  - quasi(link = "identity", variance = "constant")
  - quasibinomial(link = "logit", "probit", "cloglog", "identity", "inverse",
     "log", "1/mu^2", "sqrt")
  - quasipoisson(llink = "logit", "probit", "cloglog", "identity", "inverse",
     "log", "1/mu^2", "sqrt")
- normalize\_data: if TRUE, then response and predictors were standardized before running the local-scoring algorithm.
- X\_mean: mean of the predictor variables (only if normalize\_data = TRUE).
- X\_sd: standard deviation of the predictors (only if normalize\_data = TRUE).
- Y\_mean: mean of the response variable (only if normalize\_data = TRUE).
- Y\_sd: standard deviation of the response variable (only if normalize\_data = TRUE).

final\_model A list detailing the final GeDSgam model selected after running the local scoring algorithm. The chosen model minimizes deviance across all models generated by each local-scoring iteration. This list includes:

- model\_name: local-scoring iteration that yielded the best model. Note that when family = "gaussian", it will always correspond to iter1, as only one local-scoring iteration is conducted in this scenario. This occurs because, with family = "gaussian", the algorithm is equivalent to simply backfitting.
- DEV: the deviance for the fitted predictor model, defined as in Dimitrova et al. (2023), which for family = "gaussian" coincides with the Residual Sum of Squares.

- Y\_hat: fitted values.
  - eta: additive predictor.
  - mu: vector of means.
  - z: adjusted dependent variable.
- base\_learners: internal knots and coefficients of the final model for each of the base-learners.
- Quadratic.Fit: quadratic fit obtained via Schoenberg variation diminishing spline approximation. See for details SplineReg.
- Cubic.Fit: cubic fit obtained via Schoenberg variation diminishing spline approximation. See for details SplineReg.

predictions A list containing the predicted values obtained (linear, quadratic, and cubic). Each of the predictions contains both the additive predictor eta and the vector of means mu.

internal\_knots A list detailing the internal knots obtained for the fits of different order (linear, quadratic, and cubic).

**GGeDS** 

Generalized Geometrically Designed Spline regression estimation

# **Description**

GGeDS constructs a Geometrically Designed (univariate) variable knots spline regression model for the predictor in the context of Generalized (Non-)Linear Models, referred to as a GeDS model, for a response with a pre-specified distribution from the Exponential Family.

# Usage

```
GGeDS(
  formula,
  data,
  family = gaussian(),
  weights,
  beta,
  phi = 0.99,
  min.intknots,
  max.intknots,
```

```
q = 2L,
Xextr = NULL,
Yextr = NULL,
show.iters = FALSE,
stoptype = "SR"
)
```

# Arguments

formula	a description of the structure of the predictor model to be fitted, including the dependent and independent variables. See formula for details.
data	an optional data frame, list or environment containing the variables of the predictor model. In case the variables are not found in data, they are taken from environment(formula), typically the environment from which GGeDS is called.
family	a description of the error distribution and link function to be used in the model. This can be a character string naming a family function (e.g. "gaussian"), the family function itself (e.g. gaussian) or the result of a call to a family function (e.g. gaussian()). See family for details on family functions.
weights	an optional vector of 'prior weights' to be put on the observations in the fitting process in case the user requires weighted GeDS fitting. It is NULL by default.
beta	numeric parameter in the interval $\left[0,1\right]$ tuning the knot placement in stage A of GeDS. See details below.
phi	numeric parameter in the interval $[0,1]$ specifying the threshold for the stopping rule (model selector) in stage A of GeDS. See also stoptype and details below.
min.intknots	optional parameter allowing the user to set a minimum number of internal knots required. By default equal to zero.
max.intknots	optional parameter allowing the user to set a maximum number of internal knots to be added by the GeDS estimation algorithm. By default equal to the number of knots for the saturated GeDS model (i.e. $N-2$ , where $N$ is the number of observations).
q	numeric parameter which allows to fine-tune the stopping rule of stage A of GeDS, by default equal to 2. See details below.
Xextr	numeric vector of 2 elements representing the left-most and right-most limits of the interval embedding the observations of the independent variable. See details.
Yextr	numeric vector of 2 elements representing the left-most and right-most limits of the interval embedding the observations of the second independent variable (if the bivariate GeDS is run). See details.
show.iters	logical variable indicating whether or not to print information at each step. By default equal to FALSE.
stoptype	a character string indicating the type of GeDS stopping rule to be used. It should be either one of "SR", "RD" or "LR", partial match allowed. See details below.

# **Details**

The GGeDS function extends the GeDS methodology, recently developed by Kaishev et al. (2016) and implemented in the NGeDS function for the Normal case, to the more general GNM (GLM)

context, allowing for the response to have any distribution from the Exponential Family. Under the GeDS-GNM approach the (non-)linear predictor is viewed as a spline with variable knots which are estimated along with the regression coefficients and the order of the spline, using a two stage procedure. In stage A, a linear variable-knot spline is fitted to the data applying iteratively reweighted least squares (see IRLSfit function). In stage B, a Schoenberg variation diminishing spline approximation to the fit from stage A is constructed, thus simultaneously producing spline fits of order 2, 3 and 4, all of which are included in the output, a GeDS-Class object. A detailed description of the underlying algorithm can be found in Dimitrova et al. (2023).

As noted in formula, the argument formula allows the user to specify predictor models with two components, a spline regression (non-parametric) component involving part of the independent variables identified through the function f and an optional parametric component involving the remaining independent variables. For GGeDS only one independent variable is allowed for the spline component and arbitrary many independent variables for the parametric component of the predictor. Failure to specify the independent variable for the spline regression component through the function f will return an error. See formula.

Within the argument formula, similarly as in other R functions, it is possible to specify one or more offset variables, i.e. known terms with fixed regression coefficients equal to 1. These terms should be identified via the function offset.

The parameter beta tunes the placement of a new knot in stage A of the algorithm. Once a current second-order spline is fitted to the data the 'working' residuals (see IRLSfit) are computed and grouped by their sign. A new knot is placed at a location defined by the group for which a certain measure attains its maximum. The latter measure is defined as a weighted linear combination of the range of each group and the mean of the absolute residuals within it. The parameter beta determines the weights in this measure correspondingly as beta and 1 - beta. The higher it is, the more weight is put to the mean of the residuals and the less to the range of their corresponding x-values (see Kaishev et al., 2016, for further details).

The default values of beta are beta = 0.5 if the response is assumed to be Gaussian, beta = 0.2 if it is Poisson (or Quasipoisson), while if it is Binomial, Quasibinomial or Gamma beta = 0.1, which reflect our experience of running GeDS for different underlying functional dependencies.

The argument stoptype allows to choose between three alternative stopping rules for the knot selection in stage A of GeDS, the "RD", that stands for *Ratio of Deviances*, the "SR", that stands for *Smoothed Ratio* of deviances and the "LR", that stands for *Likelihood Ratio*. The latter is based on the difference of deviances rather than on their ratio as in the case of "RD" and "SR". Therefore "LR" can be viewed as a log likelihood ratio test performed at each iteration of the knot placement. In each of these cases the corresponding stopping criterion is compared with a threshold value phi (see below).

The argument phi provides a threshold value required for the stopping rule to exit the knot placement in stage A of GeDS. The higher the value of phi, the more knots are added under the "RD" and "SR" stopping rules contrary to the case of the stopping rule "LR" where the lower phi is, more knots are included in the spline regression. Further details for each of the three alternative stopping rules can be found in Dimitrova et al. (2023).

The argument q is an input parameter that allows to fine-tune the stopping rule in stage A. It identifies the number of consecutive iterations over which the deviance should exhibit stable convergence so as the knot placement in stage A is terminated. More precisely, under any of the rules "RD", "SR" or "LR" the deviance at the current iteration is compared to the deviance computed q iterations before, i.e. before selecting the last q knots. Setting a higher q will lead to more knots being added before exiting stage A of GeDS.

#### Value

A GeDS-Class object, i.e. a list of items that summarizes the main details of the fitted GeDS regression. See GeDS-Class for details. Some S3 methods are available in order to make these objects tractable, such as coef, deviance, knots, predict and print as well as S4 methods for lines and plot.

```

Integrate

Defined integral of GeDS objects

# **Description**

This function computes defined integrals of a fitted GeDS regression model.

# Usage

```
Integrate(object, to, from, n = 3L)
```

# **Arguments**

the GeDS-class object containing the GeDS fit which should be integrated. It object should be the result of fitting a univariate GeDS regression via NGeDS or GGeDS. numeric vector containing the upper limit(s) of integration.

to

Integrate 29

from optional numeric vector containing the lower limit(s) of integration. It should be either of size one or of the same size as the argument to. If left unspecified, by default it is set to the left-most limit of the interval embedding the observations of the independent variable.

integer value (2, 3 or 4) specifying the order (= degree + 1) of the GeDS fit to be integrated. By default equal to 3L. Non-integer values will be passed to the function as.integer.

#### **Details**

n

The function is based on the well known property (c.f. De Boor, 2001, Chapter X, formula (33)) that the integral of a linear combination of appropriately normalized B-splines is equal to the sum of its corresponding coefficients, noting that the GeDS regression is in fact such a linear combination.

Since the function is based on this property, it is designed to work only on the predictor scale in the GNM (GLM) framework.

If the argument from is a single value, then it is taken as the lower limit of integration for all the defined integrals required, whereas the upper limits of integration are the values contained in the argument to. If the arguments from and to are of similar size, the integrals (as many as the size) are computed by sequentially taking the pairs of values in the from and to vectors as limits of integration.

# **Examples**

```
# Generate a data sample for the response variable
# Y and the single covariate X
# see Dimitrova et al. (2023), section 4.1
set.seed(123)
N <- 500
f_1 \leftarrow function(x) (10*x/(1+100*x^2))*4+4
X \leftarrow sort(runif(N, min = -2, max = 2))
# Specify a model for the mean of Y to include only
# a component non-linear in X, defined by the function f_1
means \leftarrow f_1(X)
# Add (Normal) noise to the mean of Y
Y \leftarrow rnorm(N, means, sd = 0.1)
# Fit GeDS regression using NGeDS
Gmod <- NGeDS(Y ~ f(X), beta = 0.6, phi = .995, Xextr = c(-2,2))
# Compute defined integrals (in TeX style) \int_{1}^{-1} f(x)dx
# and $\int_{1}^{1} f(x)dx$
# $f$ being the quadratic fit
Integrate(Gmod, to = c(-1,1), from = 1, n = 3)
# Compute defined integrals (in TeX style) \int_{1}^{-1} f(x)dx
```

30 IRLSfit

```
# and $\int_{-1}^{1} f(x)dx$
# $f$ being the quadratic fit
Integrate(Gmod, to = c(-1,1), from = c(1,-1), n = 3)
## Not run:
## This gives an error
Integrate(Gmod, to = 1, from = c(1,-1), n = 3)
## End(Not run)
```

IRLSfit

IRLS Estimation

# Description

This function is an implementation of the IRLS estimation algorithm adjusted to the specific usage in the function SplineReg\_GLM.

# Usage

```
IRLSfit(
    x,
    y,
    weights = rep(1, nobs),
    mustart = NULL,
    offset = rep(0, nobs),
    family = gaussian(),
    control = list()
)
```

# Arguments

X	a matrix of regression functions (e.g. B-splines and/or terms of the parametric part) evaluated at the sample values of the covariate(s).
у	a vector of size $N$ containing the observed values of the response variable $y$ .
weights	an optional vector of 'prior weights' to be put on the observations in case the user requires weighted IRLS fitting. It is a vector of 1s by default.
mustart	initial values for the vector of means of the response variable in the IRLS regression estimation. Must be a vector of length ${\cal N}.$
offset	a vector of size $N$ that can be used to specify a fixed covariate to be included in the predictor model avoiding the estimation of its corresponding regression coefficient. In case more than one covariate is fixed, the user should sum the corresponding coordinates of the fixed covariates to produce one common $N$ -vector of coordinates.

IRLSfit 31

family a description of the error distribution and link function to be used in the model.

This can be a character string naming a family function (e.g. "gaussian"), the family function itself (e.g. gaussian) or the result of a call to a family function

(e.g. gaussian()). See family for details on family functions.

control a list of parameters for controlling the IRLS fitting process to be passed on to

glm. control. See glm. fit for further details.

#### **Details**

This function is a slightly modified version of the glm. fit from the package **stats** to which we refer for further details. The difference in the inputs of IRLSfit and glm. fit is that the former admits initial values only for the vector of means.

The output from IRLSfit has some additional slots compared to glm.fit. We note that the slots weights, res2 and z contain values of the IRLS weights, "working residuals" and transformed responses computed *after* the last IRLS iteration, i.e. they are based on the estimated coefficients that are returned by IRLSfit.

The source code of IRLSfit contains also some commented lines that produce useful plots at each IRLS iteration. Normally, printing these plots is time consuming, but they could be run for inspection purposes.

#### Value

A list containing:

coefficients a named vector containing the estimated regression coefficients;

residuals the 'working' residuals, that are the residuals in the final iteration of the IRLS

fit. Since cases with zero weights are omitted, their working residuals are NA;

res2 the working residuals after the final IRLS iteration. They are used within the

knot placement steps of stage A of GeDS;

fitted.values the fitted mean values, obtained by transforming the predictor by the inverse of

the link function;

rank the numeric rank of the fitted linear model;

family the family object used;

linear.predictors

the fitted predictor;

deviance a vector containing the deviances obtained at each IRLS iteration;

lastdeviance the deviance at the last IRLS iteration;

null.deviance The deviance for the null model (see glm documentation);

iter the number of IRLS iterations performed;

weights the working weights after the last IRLS iteration; prior.weights the "prior weights" (see the weights argument);

df.residual the residual degrees of freedom;

df.null the residual degrees of freedom for the null model;

y the vector of values of the response variable used in the fitting;

32 knots,GeDS

z the transformed responses computed after the last IRLS iteration; converged logical. Was the IRLS algorithm judged to have converged? boundary logical. Is the fitted value on the boundary of the attainable values?

In addition, non-empty fits will have components qr, R and effects relating to the final weighted linear fit, see lm.fit documentation.

knots.GeDS

Knots method for GeDS, GeDSboost, GeDSgam

# Description

Method for the generic function knots that allows the user to extract the vector of knots of a GeDS, GeDSboost or GeDSgam fit of a specified order contained in a GeDS-class, GeDSboost-class or GeDSgam-class object, respectively.

# Usage

```
## S3 method for class 'GeDS'
knots(Fn, n = 3L, options = c("all", "internal"), ...)
## S3 method for class 'GeDSboost'
knots(Fn, n = 3L, options = c("all", "internal"), ...)
## S3 method for class 'GeDSgam'
knots(Fn, n = 3L, options = c("all", "internal"), ...)
```

# **Arguments**

Fn	the GeDS-class, GeDSboost-class or GeDSgam-class object from which the vector of knots for the specified GeDS, FGB-GeDS or GAM-GeDS fit should be extracted.
n	integer value $(2, 3 \text{ or } 4)$ specifying the order $(= \text{degree} + 1)$ of the GeDS, FGB-GeDS or GAM-GeDS fit whose knots should be extracted. By default equal to 3L. Non-integer values will be passed to the function as.integer.
options	a character string specifying whether "all" knots, including the left-most and the right-most limits of the interval embedding the observations (the default) or only the "internal" knots should be extracted.
	potentially further arguments (required for compatibility with the definition of the generic function). Currently ignored, but with a warning.

lines, GeDS-method 33

#### **Details**

This is a method for the function knots in the **stats** package.

As GeDS-class, GeDSboost-class and GeDSgam-class objects contain three different fits (linear, quadratic and cubic), it is possible to specify the order of the GeDS fit whose knots are required via the input argument n.

#### Value

A vector in which each element represents a knot of the GeDS/FGB-GeDS/GAM-GeDS fit of the required order.

#### See Also

knots for the definition of the generic function; NGeDS, GGeDS, NGeDSboost and NGeDSgam for examples.

lines, GeDS-method

Lines method for GeDS objects.

# **Description**

Lines method for GeDS objects. Adds a GeDS curve to an existing plot.

# Usage

```
## S4 method for signature 'GeDS'
lines(
    x,
    n = 3L,
    transform = function(x) x,
    onlySpline = TRUE,
    data = data.frame(),
    ...
)
```

# **Arguments**

x a GeDS-Class object from which the GeDS fit should be extracted.

n integer value (2, 3 or 4) specifying the order (= degree + 1) of the GeDS fit that should be plotted. By default equal to 3L. Non-integer values will be passed to

the function as.integer.

transform a function that can be used to transform the scale of the Y axis. Typically it

can be the inverse of the link function if the plot is on the scale of the response

variable.

34 lines, GeDS-method

onlySpline	logical variable specifying whether only the spline component of the fitted GeDS predictor model should be plotted or alternatively also the parametric component (see formula) should be plotted.
data	an optional data.frame, list or environment containing values of the independent variables for which the GeDS predicted values should be plotted. If left empty the values are extracted from the object x itself.
	further arguments to be passed to the default lines function.

# **Details**

This method can be used to add a curve corresponding to a particular GeDS fit to an active plot.

As GeDS objects contain three different fits (linear, quadratic and cubic), it is possible to specify the order of the GeDS regression to be plotted via the input argument n.

# See Also

lines for the definition of the generic function; NGeDS and GGeDS for examples.

# **Examples**

```
# Generate a data sample for the response variable
# Y and the single covariate X
set.seed(123)
N <- 500
f_1 \leftarrow function(x) (10*x/(1+100*x^2))*4+4
X \leftarrow sort(runif(N, min = -2, max = 2))
# Specify a model for the mean of Y to include only a component
# non-linear in X, defined by the function f_1
means \leftarrow f_1(X)
# Add (Normal) noise to the mean of Y
Y \leftarrow rnorm(N, means, sd = 0.1)
# Fit a GeDS regression model using NGeDS
(Gmod \leftarrow NGeDS(Y \sim f(X), beta = 0.6, phi = 0.995, Xextr = c(-2,2)))
# Plot the GeDS third order fit (the quadratic one)
# without its corresponding Polygon
plot(Gmod, type = "none")
# Add a curve corresponding to the second order fit (the linear one)
lines(Gmod, n = 2, col = "green", lwd = 2, lty = 3)
```

NGeDS 35

NGeDS

Geometrically Designed Spline regression estimation

# Description

NGeDS constructs a Geometrically Designed variable knots spline regression model referred to as a GeDS model, for a response having a Normal distribution.

# Usage

```
NGeDS(
  formula,
  data,
  weights,
  beta = 0.5,
  phi = 0.99,
  min.intknots = 0,
  max.intknots = 500,
  q = 2,
  Xextr = NULL,
  Yextr = NULL,
  show.iters = FALSE,
  stoptype = "RD"
)
```

# Arguments

formula	a description of the structure of the model to be fitted, including the dependent and independent variables. See <a href="formula">formula</a> for details.
data	an optional data frame, list or environment containing the variables of the model. If not found in data, the variables are taken from environment(formula), typically the environment from which NGeDS is called.
weights	an optional vector of 'prior weights' to be put on the observations in the fitting process in case the user requires weighted GeDS fitting. It should be NULL or a numeric vector of the same length as the response variable in the argument formula.
beta	numeric parameter in the interval $\left[0,1\right]$ tuning the knot placement in stage A of GeDS. See details.
phi	numeric parameter in the interval $[0,1]$ specifying the threshold for the stopping rule (model selector) in stage A of GeDS. See also stoptype and details below.
min.intknots	optional parameter allowing the user to set a minimum number of internal knots required. By default equal to zero.
max.intknots	optional parameter allowing the user to set a maximum number of internal knots to be added by the GeDS estimation algorithm. By default equal to the number of knots for the saturated GeDS model.

36 NGeDS

numeric parameter which allows to fine-tune the stopping rule of stage A of q GeDS, by default equal to 2. See details. numeric vector of 2 elements representing the left-most and right-most limits of Xextr the interval embedding the observations of the first independent variable. See details. Yextr numeric vector of 2 elements representing the left-most and right-most limits of the interval embedding the observations of the second independent variable (if the bivariate GeDS is run). See details. logical variable indicating whether or not to print information at each step. show.iters a character string indicating the type of GeDS stopping rule to be used. It should stoptype be either one of "SR", "RD" or "LR", partial match allowed. See details.

#### **Details**

The NGeDS function implements the GeDS methodology, recently developed by Kaishev et al. (2016) and extended in the GGeDS function for the more general GNM, (GLM) context, allowing for the response to have any distribution from the Exponential Family. Under the GeDS approach the (non-)linear predictor is viewed as a spline with variable knots which are estimated along with the regression coefficients and the order of the spline, using a two stage algorithm. In stage A, a linear variable-knot spline is fitted to the data applying iteratively least squares regression (see 1m function). In stage B, a Schoenberg variation diminishing spline approximation to the fit from stage A is constructed, thus simultaneously producing spline fits of order 2, 3 and 4, all of which are included in the output, a GeDS-Class object.

As noted in formula, the argument formula allows the user to specify models with two components, a spline regression (non-parametric) component involving part of the independent variables identified through the function f and an optional parametric component involving the remaining independent variables. For NGeDS one or two independent variables are allowed for the spline component and arbitrary many independent variables for the parametric component. Failure to specify the independent variable for the spline regression component through the function f will return an error. See formula.

Within the argument formula, similarly as in other R functions, it is possible to specify one or more offset variables, i.e. known terms with fixed regression coefficients equal to 1. These terms should be identified via the function offset.

The parameter beta tunes the placement of a new knot in stage A of the algorithm. Once a current second-order spline is fitted to the data the regression residuals are computed and grouped by their sign. A new knot is placed at a location defined by the group for which a certain measure attains its maximum. The latter measure is defined as a weighted linear combination of the range of each group and the mean of the absolute residuals within it. The parameter beta determines the weights in this measure correspondingly as beta and 1 – beta. The higher it is, the more weight is put to the mean of the residuals and the less to the range of their corresponding x-values. The default value of beta is 0.5.

The argument stoptype allows to choose between three alternative stopping rules for the knot selection in stage A of GeDS, the "RD", that stands for *Ratio of Deviances*, the "SR", that stands for *Smoothed Ratio* of deviances and the "LR", that stands for *Likelihood Ratio*. The latter is based on the difference of deviances rather than on their ratio as in the case of "RD" and "SR". Therefore "LR" can be viewed as a log likelihood ratio test performed at each iteration of the knot placement.

NGeDS 37

In each of these cases the corresponding stopping criterion is compared with a threshold value phi (see below).

The argument phi provides a threshold value required for the stopping rule to exit the knot placement in stage A of GeDS. The higher the value of phi, the more knots are added under the "RD" and "SR" stopping rules contrary to the case of the stopping rule "LR" where the lower phi is, more knots are included in the spline regression. Further details for each of the three alternative stopping rules can be found in Dimitrova et al. (2023).

The argument q is an input parameter that allows to fine-tune the stopping rule in stage A. It identifies the number of consecutive iterations over which the deviance should exhibit stable convergence so as the knot placement in stage A is terminated. More precisely, under any of the rules "RD", "SR", or "LR", the deviance at the current iteration is compared to the deviance computed q iterations before, i.e., before selecting the last q knots. Setting a higher q will lead to more knots being added before exiting stage A of GeDS.

#### Value

GeDS-Class object, i.e. a list of items that summarizes the main details of the fitted GeDS regression. See GeDS-Class for details. Some S3 methods are available in order to make these objects tractable, such as coef, deviance, knots, predict and print as well as S4 methods for lines and plot.

NGeDSboost

Component-wise gradient boosting with NGeDS base-learners

# **Description**

NGeDSboost performs component-wise gradient boosting (Bühlmann and Yu (2003), Bühlmann and Hothorn (2007)) using normal GeD splines (i.e., fitted with NGeDS function) as base-learners (see Dimitrova et al. (2024)).

# Usage

```
NGeDSboost(
  formula,
  data,
 weights = NULL,
  normalize_data = FALSE,
  family = mboost::Gaussian(),
  initial_learner = TRUE,
  int.knots_init = 2L,
 min_iterations,
 max_iterations,
  shrinkage = 1,
  phi_boost_exit = 0.995,
  q_boost = 2L,
  beta = 0.5,
  phi = 0.99,
  internal_knots = 500L,
  q = 2L,
  higher_order = TRUE
)
```

# **Arguments**

formula

a description of the structure of the model to be fitted, including the dependent and independent variables. Unlike NGeDS and GGeDS, the formula specified allows for multiple additive GeD spline regression components (as well as linear

components) to be included (e.g.,  $Y \sim f(X1) + f(X2) + X3$ ). See formula for further details.

data a data frame containing the variables referenced in the formula.

weights an optional vector of 'prior weights' to be put on the observations during the

fitting process. It should be  $\ensuremath{\mathsf{NULL}}$  or a numeric vector of the same length as the

response variable defined in the formula.

normalize\_data a logical that defines whether the data should be normalized (standardized) be-

fore fitting the baseline linear model, i.e., before running the FGB algorithm. Normalizing the data involves scaling the predictor variables to have a mean of 0 and a standard deviation of 1. This process alters the scale and interpretation

of the knots and coefficients estimated. Default is equal to FALSE.

family determines the loss function to be optimized by the boosting algorithm. In

case initial\_learner = FALSE it also determines the corresponding empirical risk minimizer to be used as offset initial learner. By default, it is set to mboost::Gaussian(). Users can specify any Family object from the **mboost** 

package.

initial\_learner

a logical value. If set to TRUE, the model's initial learner will be a normal GeD spline. If set to FALSE, then the initial predictor will consist of the empirical risk minimizer corresponding to the specified family. Note that if initial\_learner

= TRUE, family must be mboost::Gaussian().

int.knots\_init optional parameter allowing the user to set a maximum number of internal knots

to be added by the initial GeDS learner in case initial\_learner = TRUE. De-

fault is equal to 2L.

min\_iterations optional parameter to manually set a minimum number of boosting iterations to

be run. If not specified, it defaults to 0L.

max\_iterations optional parameter to manually set the maximum number of boosting itera-

tions to be run. If not specified, it defaults to 100L. This setting serves as a fallback when the stopping rule, based on consecutive deviances and tuned by phi\_boost\_exit and q\_boost, does not trigger an earlier termination (see Dimitrova et al. (2024)). Therefore, users can increase/decrease the number of boosting iterations, by increasing/decreasing the value phi\_boost\_exit

and/or# q\_boost, or directly specify max\_iterations.

shrinkage numeric parameter in the interval [0, 1] defining the step size or shrinkage pa-

rameter. This controls the size of the steps taken in the direction of the gradient of the loss function. In other words, the magnitude of the update each new

iteration contributes to the final model. Default is equal to 1.

phi\_boost\_exit numeric parameter in the interval [0, 1] specifying the threshold for the boosting

iterations stopping rule. Default is equal to 0.995.

q\_boost numeric parameter which allows to fine-tune the boosting iterations stopping

rule, by default equal to 2L.

beta numeric parameter in the interval [0,1] tuning the knot placement in stage A of

GeDS. Default is equal to 0.5. See details in NGeDS.

phi numeric parameter in the interval [0, 1] specifying the threshold for the stopping

rule (model selector) in stage A of GeDS. Default is equal to 0.99. See details

in NGeDS.

internal\_knots The maximum number of internal knots that can be added by the GeDS base-

learners in each boosting iteration, effectively setting the value of max.intknots

in NGeDS at each boosting iteration. Default is 500L.

q numeric parameter which allows to fine-tune the stopping rule of stage A of

GeDS, by default equal to 2L. See details in NGeDS.

higher\_order a logical that defines whether to compute the higher order fits (quadratic and

cubic) after the FGB algorithm is run. Default is TRUE.

#### Details

The NGeDSboost function implements functional gradient boosting algorithm for some pre-defined loss function, using linear GeD splines as base learners. At each boosting iteration, the negative gradient vector is fitted through the base procedure encapsulated within the NGeDS function. The latter constructs a Geometrically Designed variable knots spline regression model for a response having a Normal distribution. The FGB algorithm yields a final linear fit. Higher order fits (quadratic and cubic) are then computed by calculating the Schoenberg's variation diminishing spline (VDS) approximation of the linear fit.

On the one hand, NGeDSboost includes all the parameters of NGeDS, which in this case tune the base-learner fit at each boosting iteration. On the other hand, NGeDSboost includes some additional parameters proper to the FGB procedure. We describe the main ones as follows.

First, family allows to specify the loss function and corresponding risk function to be optimized by the boosting algorithm. If initial\_learner = FALSE, the initial learner employed will be the empirical risk minimizer corresponding to the family chosen. If initial\_learner = TRUE then the initial learner will be an NGeDS fit with maximum number of internal knots equal to int.knots\_init.

shrinkage tunes the step length/shrinkage parameter which helps to control the learning rate of the model. In other words, when a new base learner is added to the ensemble, its contribution to the final prediction is multiplied by the shrinkage parameter. The smaller shrinkage is, the slower/more gradual the learning process will be, and viceversa.

The number of boosting iterations is controlled by a *Ratio of Deviances* stopping rule similar to the one presented for GGeDS. In the same way phi and q tune the stopping rule of GGeDS, phi\_boost\_exit and q\_boost tune the stopping rule of NGeDSboost. The user can also manually control the number of boosting iterations through min\_iterations and max\_iterations.

## Value

GeDSboost-Class object, i.e. a list of items that summarizes the main details of the fitted FGB-GeDS model. See GeDSboost-Class for details. Some S3 methods are available in order to make these objects tractable, such as coef, knots, print and predict. Also variable importance measures (bl\_imp) and improved plotting facilities (visualize\_boosting).

## **Description**

Implements the Local Scoring Algorithm (Hastie and Tibshirani (1986)), applying normal GeD splines (i.e., NGeDS function) to fit the targets within the backfitting iterations.

## Usage

```
NGeDSgam(
  formula,
  data,
 weights = NULL,
  normalize_data = FALSE,
  family = "gaussian",
 min_iterations,
 max_iterations,
  phi_gam_exit = 0.995,
  q_gam = 2,
  beta = 0.5,
  phi = 0.99,
  internal_knots = 500,
  q = 2,
  higher_order = TRUE
)
```

## **Arguments**

formula	a description of the structure	of the model to be	fitted, including	ng the dependent

and independent variables. Unlike NGeDS and GGeDS, the formula specified allows for multiple additive GeD spline regression components (as well as linear components) to be included (e.g.,  $Y \sim f(X1) + f(X2) + X3$ ). See formula for

further details.

data a data frame containing the variables referenced in the formula.

weights an optional vector of 'prior weights' to be put on the observations during the fitting process. It should be NULL or a numeric vector of the same length as the

response variable defined in the formula.

normalize\_data a logical that defines whether the data should be normalized (standardized) be-

fore fitting the baseline linear model, i.e., before running the local-scoring algorithm. Normalizing the data involves scaling the predictor variables to have a mean of 0 and a standard deviation of 1. This process alters the scale and

interpretation of the knots and coefficients estimated. Default is equal to FALSE.

family a character string indicating the response variable distribution and link function to be used. Default is "gaussian". This should be a character or a family object.

min\_iterations optional parameter to manually set a minimum number of boosting iterations to

be run. If not specified, it defaults to 0L.

max\_iterations optional parameter to manually set the maximum number of boosting iterations to be run. If not specified, it defaults to 100L. This setting serves as a

fallback when the stopping rule, based on consecutive deviances and tuned by phi\_gam\_exit and q\_gam, does not trigger an earlier termination (see Dimitrova

	et al. (2024)). Therefore, users can increase/decrease the number of boosting iterations, by increasing/decreasing the value phi_gam_exit and/or q_gam, or directly specify max_iterations.
phi_gam_exit	Convergence threshold for local-scoring and backfitting. Both algorithms stop when the relative change in the deviance is below this threshold. Default is 0.995.
q_gam	numeric parameter which allows to fine-tune the stopping rule of local-scoring/backfitting, by default equal to 2L.
beta	numeric parameter in the interval $[0,1]$ tuning the knot placement in stage A of GeDS. Default is equal to 0.5. See details in NGeDS.
phi	numeric parameter in the interval $[0,1]$ specifying the threshold for the stopping rule (model selector) in stage A of GeDS. Default is equal to 0.99. See details in NGeDS.
internal_knots	The maximum number of internal knots that can be added by the GeDS base-learners in each boosting iteration, effectively setting the value of max.intknots in NGeDS at each backfitting iteration. Default is 500L.
q	numeric parameter which allows to fine-tune the stopping rule of stage A of GeDS, by default equal to 2L. See details in NGeDS.
higher_order	a logical that defines whether to compute the higher order fits (quadratic and cubic) after the local-scoring algorithm is run. Default is TRUE.

#### **Details**

The NGeDSgam function employs the local scoring algorithm to fit a Generalized Additive Model (GAM). This algorithm iteratively fits weighted additive models by backfitting. Normal linear GeD splines, as well as linear learners, are supported as function smoothers within the backfitting algorithm. The local-scoring algorithm ultimately produces a linear fit. Higher order fits (quadratic and cubic) are then computed by calculating the Schoenberg's variation diminishing spline (VDS) approximation of the linear fit.

On the one hand, NGeDSgam includes all the parameters of NGeDS, which in this case tune the smoother fit at each backfitting iteration. On the other hand, NGeDSgam includes some additional parameters proper to the local-scoring procedure. We describe the main ones as follows.

The family chosen determines the link function, adjusted dependent variable and weights to be used in the local-scoring algorithm. The number of local-scoring and backfitting iterations is controlled by a *Ratio of Deviances* stopping rule similar to the one presented for GGeDS. In the same way phi and q tune the stopping rule of GGeDS, phi\_boost\_exit and q\_boost tune the stopping rule of NGeDSgam. The user can also manually control the number of local-scoring iterations through min\_iterations and max\_iterations.

## Value

GeDSgam-Class object, i.e. a list of items that summarizes the main details of the fitted GAM-GeDS model. See GeDSgam-Class for details. Some S3 methods are available in order to make these objects tractable, such as coef, knots, print and predict.

Plot method for GeDS objects.

# **Description**

Plot method for GeDS objects. Plots GeDS fits.

# Usage

```
## S4 method for signature 'GeDS'
plot(
    x,
    f = NULL,
    which,
    DEV = FALSE,
    ask = FALSE,
    main,
    legend.pos = "topright",
    new.window = FALSE,
    wait = 0.5,
    n = 3L,
    type = c("none", "Polygon", "NCI", "ACI"),
    ...
)
```

# **Arguments**

X	a GeDS-Class object from which the GeDS fit(s) should be extracted.
f	(optional) specifies the underlying function or generating process to which the model was fit. This parameter is useful if the user wishes to plot the specified function/process alongside the model fit and the data
which	a numeric vector specifying the iterations of stage A for which the corresponding GeDS fits should be plotted. It has to be a subset of 1:nrow(x\$stored). See details.
DEV	logical variable specifying whether a plot representing the deviance at each iter-

ation of stage A should be produced or not.

48 plot,GeDS-method

ask logical variable specifying whether the user should be prompted before changing the plot page. optional character string to be used as a title of the plot. main the position of the legend within the panel. See legend for details. legend.pos logical variable specifying whether the plot should be shown in a new window new.window or in the active one. time, in seconds, the system should wait before plotting a new page. Ignored if wait ask = TRUE. integer value (2, 3 or 4) specifying the order (= degree + 1) of the GeDS fit that n should be plotted. By default equal to 3L. Non-integer values will be passed to the function as.integer. type character string specifying the type of plot required. Should be set either to "Polygon" if the user wants to get also the control polygon of the GeDS fit, "NCI" or "ACI" if 95% confidence bands for the predictions should be plotted (see details) or "none" if only the fitted GeDS curve should be plotted. Applies only when plotting a univariate spline regression. further arguments to be passed to the plot.default function. . . .

#### **Details**

This method is provided in order to allow the user to plot the GeDS fits contained in the GeDS-Class objects.

Since in Stage A of the GeDS algorithm the knots of a linear spline fit are sequentially located, one at a time, the user may wish to visually inspect this process using the argument which. The latter specifies a particular iteration number (or a vector of such numbers) for which the corresponding linear fit(s) should be plotted. The ask and wait arguments can help the user to manage these pages.

By means of ask the user can determine for how long each page should appear on the screen. Pages are sequentially replaced by pressing the enter button.

Note that, in order to ensure stability, if the object was produced by the function GGeDS, plotting intermediate fits of stage A is allowed only if n = 2, in contrast to objects produced by NGeDS for which plotting intermediate results is allowed also for n = 2 or 3 results.

The confidence intervals obtained by setting type = "NCI" are approximate local bands obtained considering the knots as fixed constants. Hence the columns of the design matrix are seen as covariates and standard methodology relying on the se.fit option of predict.lm or predict.glm is applied.

Setting type = "ACI", asymptotic confidence intervals are plotted. This option is applicable only if the canonical link function has been used in the fitting procedure.

PPolyRep

Piecewise Polynomial Spline Representation

## Description

The function converts a GeDS fit which has a B-spline representation to a piecewise polynomial form.

# Usage

```
PPolyRep(object, n = 3)
```

## **Arguments**

object the GeDS-class where the GeDS fit to be converted is found.

n integer value (2, 3 or 4) specifying the order (= degree +1) of the GeDS fit

which should be converted to a piecewise polynomial form. By default equal to

3L. Non-integer values will be passed to the function as.integer.

## **Details**

This function converts a selected GeDS fit from a GeDS-class object represented in terms of B-splines into an object where the fit is represented in terms of piecewise polynomials.

The function wraps polySpline in order to let it accept GeDS-class objects as input. Hence the function provides a useful link between the package **GeDS** and the package **splines**, allowing the user to take advantage of the functions provided in the **splines** package.

# Value

An object that inherits from classes "spline" and "polySpline". It is a list whose arguments are:

knots a vector of size k + 2 containing the complete set of knots (internal knots plus

the limits of the interval) of the GeDS fit.

coefficients a  $(k+2) \times n$  matrix containing the coefficients of the polynomials in the required

piecewise polynomial representation.

predict.GeDS 51

#### Note

Let us note that the first k+1 rows of the matrix contain the n coefficients of the k+1 consecutive pieces of the piecewise polynomial representation. The last (k+2)-th row is extraneous and it appears as a result of the use of the function polySpline.

```
# Generate a data sample for the response variable
# Y and the single covariate X
set.seed(123)
N <- 500
f_1 \leftarrow function(x) (10*x/(1+100*x^2))*4+4
X \leftarrow sort(runif(N, min = -2, max = 2))
# Specify a model for the mean of Y to include only
# a component non-linear in X, defined by the function f_1
means <- f_1(X)
# Add (Normal) noise to the mean of Y
Y \leftarrow rnorm(N, means, sd = 0.1)
# Fit a Normal GeDS regression using NGeDS
Gmod <- NGeDS(Y ~ f(X), beta = 0.6, phi = 0.995, Xextr = c(-2,2))
# construct the PP representation of the cubic GeDS fit
# and apply some functions of the package splines
Polymod <- PPolyRep(Gmod, 4)
require(splines)
class(Polymod)
splineKnots(Polymod)
knots(Gmod, n = 4)
plot(Polymod)
# Generate a plot showing the PP representation
# based on the same example

coeffs <- coef(Polymod)</pre>
plot(Gmod, n = 4, legend = FALSE, main = "Cubic Curves")
cols <- sample(heat.colors(length(knt)), length(knt))</pre>
for(i in 1:(length(knt))){
  curve(coeffs[i,1] + coeffs[i,2]*(x - knt[i])+
          coeffs[i,3]*(x - knt[i])^2+
        coeffs[i,4]*(x - knt[i])^3,
        add = TRUE, col = cols[i])
  abline(v = knt[i])
}
```

52 predict.GeDS

## **Description**

This is a user friendly method to compute predictions from GeDS objects.

## **Usage**

```
## S3 method for class 'GeDS'
predict(object, newdata, type = c("response", "link", "terms"), n = 3L, ...)
```

## **Arguments**

object the GeDS-class object for which the computation of the predicted values is required. an optional data.frame, list or environment containing values of the indenewdata pendent variables for which predicted values of the predictor model (including the GeDS and the parametric components) should be computed. If left empty the values are extracted from the object x itself. character string indicating the type of prediction required. By default it is equal type

to "response", i.e. the result is on the scale of the response variable. See details

for the other options.

integer value (2, 3 or 4) specifying the order (= degree + 1) of the GeDS fit n

whose predicted values should be computed. By default equal to 3L. Non-integer

values will be passed to the function as.integer.

potentially further arguments (required by the definition of the generic function).

They are ignored, but with a warning.

## **Details**

This is a method for the function predict that allows the user to handle GeDS-Class objects.

In analogy with the function predict.glm in the stats package, the user can specify the scale on which the predictions should be computed through the argument type. If the predictions are required to be on the scale of the response variable, the user should set type = "response", which is the default. Alternatively if one wants the predictions to be on the predictor scale, it is necessary to set type = "link". By specifying type = "terms", it is possible to inspect the predicted values separately for each single independent variable which enter either the GeD spline component or the parametric component of the predictor model. In this case the returned result is a matrix whose columns correspond to the terms supplied via newdata or extracted from the object.

As GeDS objects contain three different fits (linear, quadratic and cubic), it is possible to specify the order for which GeDS predictions are required via the input argument n.

#### Value

A numeric vector corresponding to the predicted values (if type = "link" or type = "response"). If type = "terms" a numeric matrix with a column per term.

predict for the standard definition; GGeDS for examples.

predict.GeDSboost, gam Predict method for GeDSboost, GeDSgam

# Description

This method computes predictions from GeDSboost and GeDSgam objects. It is designed to be user-friendly and accommodate different orders of the GeDSboost or GeDSgam fits.

## Usage

```
## S3 method for class 'GeDSboost'
predict(object, newdata, n = 2L, ...)
## S3 method for class 'GeDSgam'
predict(object, newdata, n = 2L, ...)
```

# **Arguments**

object The GeDSboost-class or GeDSgam-class object.

An optional data frame for prediction.

The order of the GeDS fit (2 for linear, 3 for quadratic, and 4 for cubic). Default is 2.

potentially further arguments.

# Value

Numeric vector of predictions (vector of means).

print.GeDS

Print method for GeDS, GeDSboost, GeDSgam

# **Description**

Method for the generic function print that allows to print on screen the main information related to the fitted predictor model that can be extracted from a GeDS-class, GeDSboost-class or GeDSgam-class object.

## Usage

```
## S3 method for class 'GeDS'
print(x, digits = max(3L, getOption("digits") - 3L), ...)
## S3 method for class 'GeDSboost'
print(x, digits = max(3L, getOption("digits") - 3L), ...)
## S3 method for class 'GeDSgam'
print(x, digits = max(3L, getOption("digits") - 3L), ...)
```

SplineReg SplineReg

# Arguments

Х	the GeDS-class, GeDSboost-class or GeDSgam-class object for which the main information should be printed on screen.
digits	number of digits to be printed.
	potentially further arguments (required by the definition of the generic function).

## **Details**

This method allows to print on screen basic information related to the fitted predictor model such as the function call, the number of internal knots for the linear GeDS/FGB-GeDS/GAM-GeDS fit and the deviances for the three (linear, quadratic and cubic) fitted predictor models embedded in the GeDSboost-class or GeDSgam-class object.

## Value

This function returns (invisibly) the same input object, but adding the slot Print that contains the three sub-slots:

Nknots the number of internal knots of the linear GeDS/FGB-GeDS/GAM-GeDS fit

Deviances the deviances of the three (linear, quadratic and cubic) GeDS/FGB-GeDS/GAM-

GeDS fits

Call the call to the function that produced the x object

## See Also

print for the standard definition.

SplineReg	Estimation of the coefficients of a predictor model with spline and pos-
	sibly parametric components.

# **Description**

Functions that estimate the coefficients of a predictor model involving a spline component and possibly a parametric component applying (Iteratively Re-weighted) Least Squares (IR)LS iteration.

# Usage

```
SplineReg_LM(
    X,
    Y,
    Z = NULL,
    offset = rep(0, NROW(X)),
    weights = rep(1, length(Y)),
    InterKnots,
    n,
```

SplineReg 55

```
extr = range(X),
  prob = 0.95,
  coefficients = NULL
)
SplineReg_GLM(
  Χ,
  Υ,
  Ζ,
  offset = rep(0, nobs),
  weights = rep(1, length(Y)),
  InterKnots,
  n,
  extr = range(X),
  family,
  mustart,
  inits = NULL,
  etastart = NULL
)
```

## **Arguments**

Ζ

n

X a numeric vector containing N sample values of the covariate chosen to enter the spline regression component of the predictor model.

Y a vector of size N containing the observed values of the response variable y.

a design matrix with N rows containing other covariates selected to enter the parametric component of the predictor model (see formula). If no such covariates are selected, it is set to NULL by default.

offset a vector of size N that can be used to specify a fixed covariate to be included in the predictor model avoiding the estimation of its corresponding regression coefficient. In case more than one covariate is fixed, the user should sum the corresponding coordinates of the fixed covariates to produce one common N-vector of coordinates. The argument offset is particularly useful in Splinereg\_GLM

if the link function used is not the identity.

weights an optional vector of 'prior weights' to be put on the observations in the fitting

process in case the user requires weighted fitting. It is a vector of 1s by default.

InterKnots a numeric vector containing the locations of the internal knots necessary to compute the B-splines. In GeDS these are the internal knots in a current iteration of

stage A.

integer value specifying the order of the spline to be evaluated. It should be 2 (linear spline), 3 (quadratic spline) or 4 (cubic spline). Non-integer values will

be passed to the function as.integer.

extr optional numeric vector of 2 elements representing the left-most and right-most

limits of the interval embedding the sample values of X. By default equal corre-

spondingly to the smallest and largest values of X.

prob the confidence level to be used for the confidence bands in the SplineReg\_LM

fit. See details below.

56 SplineReg

coefficients	optional vector of spline coefficients. If provided, SplineReg computes only the corresponding predicted values.
family	a description of the error distribution and link function to be used in the model. This can be a character string naming a family function, a family function or the result of a call to a family function. See family for details of family functions.
mustart	initial values for the vector of means in the IRLS estimation. Must be a vector of length $N.$
inits	a numeric vector of length length(InterKnots) + $n$ + NCOL(Z) providing initial values for the coefficients, to be used in the IRLS estimation (alternative to providing the mustart vector).
etastart	initial values for the predictor in the IRLS estimation (alternative to providing either inits or mustart). Must be a vector of length $N$ .

#### **Details**

The functions estimate the coefficients of a predictor model with a spline component (and possibly a parametric component) for a given, fixed order and vector of knots of the spline and a specified distribution of the response variable (from the Exponential Family). The functions SplineReg\_LM and SplineReg\_GLM are based correspondingly on LS and IRLS and used correspondingly in NGeDS and GGeDS, to estimate the coefficients of the final GeDS fits of stage B, after their knots have been positioned to coincide with the Greville abscissas of the knots of the linear fit from stage A (see Dimitrova et al. 2023). Additional inference related quantities are also computed (see Value below). The function SplineReg\_GLM is also used to estimate the coefficients of the linear GeDS fit of stage A within GGeDS, whereas in NGeDS this estimation is performed internally leading to faster R code.

In addition SplineReg\_LM computes some useful quantities among which confidence intervals and the Control Polygon (see Section 2 of Kaishev et al. 2016).

The confidence intervals contained in the output slot NCI are approximate local bands obtained considering the knots as fixed constants. Hence the columns of the design matrix are seen as covariates and standard methodology relying on the se.fit option of predict.lm or predict.glm is used. In the ACI slot, asymptotic confidence intervals are provided, following Kaishev et al (2006).

As mentioned, SplineReg\_GLM is intensively used in Stage A of the GeDS algorithm implemented in GGeDS and in order to make it as fast as possible input data validation is mild. Hence it is expected that the user checks carefully the input parameters before using SplineReg\_GLM. The "Residuals" in the output of this function are similar to the so called "working residuals" in the glm function. "Residuals" are the residuals  $r_i$  used in the knot placement procedure, i.e.

$$r_i = (y_i - \hat{\mu}_i) \frac{d\mu_i}{d\eta_i},$$

but in contrast to glm "working residuals", they are computed using the final IRLS fitted  $\hat{\mu}_i$ . "Residuals" are then used in locating the knots of the linear spline fit of Stage A.

In SplineReg\_GLM confidence intervals are not computed.

#### Value

A list containing:

SplineReg 57

Theta	a vector containing the fitted coefficients of the spline regression component and the parametric component of the predictor model.
Predicted	a vector of $N$ predicted mean values of the response variable computed at the sample values of the covariate(s).
Residuals	a vector containing the normal regression residuals if SplineReg_LM is called or the residuals described in Details if SplineReg_GLM is called.
RSS	the deviance for the fitted predictor model, defined as in Dimitrova et al. (2023), which for SplineReg_LM coincides with the Residual Sum of Squares.
NCI	a list containing the lower (Low) and upper (Upp) limits of the approximate confidence intervals computed at the sample values of the covariate(s). See details above.
Basis	the matrix of B-spline regression functions and the covariates of the parametric part evaluated at the sample values of the covariate(s).
Polygon	a list containing x-y coordinates ("Kn" and "Thetas") of the vertices of the Control Polygon, see Dimitrova et al. $(2023)$ .
deviance	a vector containing deviances computed at each IRLS step (computed only with the $SplineReg\_GLM$ ).
temporary	the result of the function <code>lmif</code> SplineReg_LM is used or the output of the function <code>IRLSfit</code> (which is similar to the output from <code>glm.fit</code> ), if SplineReg_GLM is used.

58 UnivariateFitters

UnivariateFitters

Functions used to fit GeDS objects w/univariate spline regression component

# **Description**

These are computing engines called by NGeDS and GGeDS, needed for the underlying fitting procedures.

# Usage

```
UnivariateFitter(
 Χ,
  Υ,
  Z = NULL
 offset = rep(0, NROW(Y)),
 weights = rep(1, length(X)),
  beta = 0.5,
  phi = 0.5,
 min.intknots = 0,
 max.intknots = 300,
  q = 2,
  extr = range(X),
  show.iters = FALSE,
  tol = as.double(1e-12),
  stoptype = c("SR", "RD", "LR")
)
GenUnivariateFitter(
 Χ,
 Υ,
  Z = NULL
  offset = rep(0, NROW(Y)),
 weights = rep(1, length(X)),
  family = gaussian(),
  beta = 0.5,
  phi = 0.5,
  min.intknots = 0,
 max.intknots = 300,
  q = 2,
  extr = range(X),
  show.iters = F,
  tol = as.double(1e-12),
  stoptype = c("SR", "RD", "LR")
)
```

UnivariateFitters 59

Arguments	
Χ	a numeric vector containing $N$ sample values of the covariate chosen to enter the spline regression component of the predictor model.
Υ	a vector of size $N$ containing the observed values of the response variable $y$ .
Z	a design matrix with $N$ rows containing other covariates selected to enter the parametric component of the predictor model (see <code>formula</code> ). If no such covariates are selected, it is set to NULL by default.
offset	a vector of size $N$ that can be used to specify a fixed covariate to be included in the predictor model avoiding the estimation of its corresponding regression coefficient. In case more than one covariate is fixed, the user should sum the corresponding coordinates of the fixed covariates to produce one common $N$ -vector of coordinates. The offset argument is particularly useful when using GenUnivariateFitter if the link function used is not the identity.
weights	an optional vector of size $N$ of 'prior weights' to be put on the observations in the fitting process in case the user requires weighted GeDS fitting. It is NULL by default.
beta	numeric parameter in the interval $[0,1]$ tuning the knot placement in stage A of GeDS. See the description of NGeDS or GGeDS.
phi	numeric parameter in the interval $[0,1]$ specifying the threshold for the stopping rule (model selector) in stage A of GeDS. See also stoptype and details in the description of NGeDS or GGeDS.
min.intknots	optional parameter allowing the user to set a minimum number of internal knots required. By default equal to zero.
max.intknots	optional parameter allowing the user to set a maximum number of internal knots to be added by the GeDS estimation algorithm. By default equal to the number of internal knots $\kappa$ for the saturated GeDS model (i.e. $\kappa=N-2$ ).
q	numeric parameter which allows to fine-tune the stopping rule of stage A of GeDS, by default equal to 2. See details in the description of NGeDS or GGeDS.
extr	numeric vector of 2 elements representing the left-most and right-most limits of the interval embedding the sample values of X. By default equal correspondingly to the smallest and largest values of X.
show.iters	logical variable indicating whether or not to print information at each step. By default equal to FALSE.
tol	numeric value indicating the tolerance to be used in the knot placement steps in stage A. By default equal to 1E-12. See details below.
stoptype	a character string indicating the type of GeDS stopping rule to be used. It should be either "SR", "RD" or "LR", partial match allowed. See details of NGeDS or GGeDS.
family	a description of the error distribution and link function to be used in the model.

This can be a character string naming a family function (e.g. "gaussian"), the family function itself (e.g. gaussian) or the result of a call to a family function

(e.g. gaussian()). See family for details on family functions.

60 UnivariateFitters

#### **Details**

The functions UnivariateFitter and GenUnivariateFitter are in general not intended to be used directly, they should be called through NGeDS and GGeDS. However, in case there is a need for multiple GeDS fitting (as may be the case e.g. in Monte Carlo simulations) it may be efficient to use the fitters outside the main functions.

The argument tol is used in the knot placement procedure of stage A of the GeDS algorithm in order to check whether the current knot  $\delta^*$  is set at an acceptable location or not. If there exists a knot  $\delta_i$  such that  $|\delta^* - \delta_i| < \text{tol}$ ,  $\delta^*$ , then the new knot is considered to be coalescent with an existing one, it is discarded and the algorithm seeks alternative knot locations. By default it is equal to 1e-12.

See NGeDS and GGeDS, Kaishev et al. (2016) and Dimitrova et al. (2023) for further details.

#### Value

A GeDS-Class object, but without the Formula, extcall, terms and znames slots.

visualize\_boosting

Visualize Boosting Iterations

## **Description**

This function plots the NGeDSboost fit to the data at the beginning of a given boosting iteration and then plots the subsequent NGeDS fit on the corresponding residual (negative gradient). Note: Applicable only for NGeDSboost models with one covariate and family = mboost::Gaussian().

# Usage

```
## S3 method for class 'GeDSboost'
visualize_boosting(M, object)
```

# Arguments

M Numeric, specifies the iteration number.

object A GeDSboost-Class object.

```
# Load packages
library(GeDS)

# Generate a data sample for the response variable
# Y and the single covariate X
set.seed(123)
N <- 500
f_1 <- function(x) (10*x/(1+100*x^2))*4+4</pre>
```
